Amendments to the Specification

Please replace the paragraph spanning from p.4, line 15 - p.5, line 11 with the following amended paragraph:

In another embodiment, the invention provides a transgenic mouse comprising a somatic cell, comprising:

- (a) in a first chromosome of a chromosome pair, a polynucleotide comprising a promoter operably linked to a chimeric sequence encoding an N-terminal portion of a first marker and a C-terminal portion of a second marker separated by a recombinase target site;
- (b) at a homologous location of a second chromosome of the chromosome pair, a polynucleotide comprising a promoter operably linked to a chimeric sequence encoding an N-terminal portion of the second marker and a C-terminal portion of the first marker separated by a recombinase target site; and
- (c) a recombinase expressed by the cell, and which promotes recombination between the target sites of the first and second chromosomes;

wherein recombinase-promoted somatic mitotic recombination between the target sites yields alternative pairs of X- or Z-segregated progeny cells,

wherein the X-segregated progeny cells comprise a first progeny cell comprising the first chromosome, and a recombined variant of the second chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the first-second marker; and a second progeny cell comprising the second chromosome, and a recombined variant of the first chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the second first marker, and

wherein the Z-segregated progeny cells comprise a first progeny cell comprising the first chromosome and the second chromosome, and a second progeny cell comprising a recombined variant of the first chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the first marker; and a recombined variant of the second chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the second marker,

wherein the first X-segregated progeny cell produces a <u>first-second</u> marker-specific signal, the second X-segregated progeny cell produces a <u>second</u> first marker-specific signal, the

first Z-segregated progeny cell produces neither a first nor second marker-specific signal, and the second Z-segregated progeny cell produces both a first and a second marker specific-signal.

Please replace the paragraph spanning from p.5, line 13 - p.6, line 12 with the following amended paragraph:

In another embodiment, the invention provides a method to generate and mark chromosome recombination in somatic cells in a subject mouse by:

- (a) introducing in a first chromosome of a chromosome pair of a pluripotent cell, a polynucleotide comprising a promoter operably linked to a chimeric sequence encoding an N-terminal portion of a first marker and a C-terminal portion of a second marker separated by a recombinase target site;
- (b) introducing at a homologous location of a second chromosome of the chromosome pair of the pluripotent cell, a polynucleotide comprising a promoter operably linked to a chimeric sequence encoding an N-terminal portion of the second marker and a C-terminal portion of the first marker separated by a recombinase target site,

wherein the cell expresses a recombinase which promotes recombination between the target sites of the first and second chromosomes; and

(c) growing the cell to obtain a mouse comprising differentiated progeny cells of the pluripotent cell, wherein recombinase-promoted somatic mitotic recombination between the target sites in a differentiated progeny cell yields alternative pairs of X- or Z-segregated progeny cells.

wherein the X-segregated progeny cells comprise a first progeny cell comprising the first chromosome, and a recombined variant of the second chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the first second marker; and a second progeny cell comprising the second chromosome, and a recombined variant of the first chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the second first marker, and

wherein the Z-segregated progeny cells comprise a first progeny cell comprising the first chromosome and the second chromosome, and a second progeny cell comprising a recombined variant of the first chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the first marker; and a recombined variant of the second

chromosome comprising the promoter operably linked to a sequence encoding the N- and C-terminal portions of the second marker,

wherein the first X-segregated progeny cell produces a first-second marker-specific signal, the second X-segregated progeny cell produces a second first marker-specific signal, the first Z-segregated progeny cell produces neither a first nor second marker-specific signal, and the second Z-segregated progeny cell produces both a first and a second marker specific-signal.
